## Foreword

Like many countries, Canada has experienced a population that has been aging at an increasing rate. The aging of the Canadian population has increased especially since the inception of the Old Age Security (OAS) program in 1952. Increasing life expectancies, the aging of the baby boomers and fertility rates that have been below replacement levels for some time are the predominant factors that have contributed to a large increase in the proportion of elderly in the Canadian population, and this increase is expected to continue over the next 30 to 50 years. As a result, the population at ages 65 and over is expected to more than double from 2003 to 2030, and as a proportion of the total population will grow from 13% of the population to 23% by 2030 and then to 25% by 2050. Older age groups will experience even higher rates of growth. As an example, those aged 85 and over, which now represent 1.5% of the population, are expected to represent 2.7% of the population by 2030 and 5.1% of the population by 2050. An increasing proportion of elderly will create challenges especially in the financing of social and health programs that are financed from general tax revenues. Under the OAS program, which is financed from general revenues, the number of recipients of the basic pension is expected to more than double from 4.0 million in 2003 to 8.9 million in 2030.

Historically, the level and age trajectory of mortality rates at advanced ages in Canada have not been readily and precisely measured due to problems concerning the reliability of data on deaths and on population counts beyond a certain point in official vital statistics. For instance, Life Tables for Canada (LTC) published by Statistics Canada are based on Census data and on the national system of vital statistics. As the OAS program provides the payment of old age basic benefits to almost all Canadians aged 65 and over, the availability of an administrative OAS beneficiaries database allows the more accurate measurement of the level and trend in mortality experienced by the oldest portion of the Canadian population. This study will indicate how current trends in mortality at older ages compare with past trends and how the resulting shape of the survival curve is changing as income increases.

Intuitively, individuals with a higher standard of living are expected to experience lower mortality than those with a lower standard of living due to an overall healthier lifestyle combined with a higher income. In addition to studying the overall mortality of older Canadians by age and sex, this study also analyses mortality in terms of income, which is the most common variable used in defining an individual's socio-economic status. For this study, the measure of income was determined from the type and amount of monthly OAS program benefits received over the period of the study. These benefits include the cases where the basic OAS benefit was reduced by the clawback provision because of high income or was increased through the income-tested Guaranteed Income Supplement (GIS) because of low income.

## I. Executive Summary

### A. Purpose

This study is the second mortality study published by the Office of the Chief Actuary (OCA). It presents estimates of the level of mortality as measured from the mortality experience of Canadian resident beneficiaries of the Old Age Security (OAS) program who were aged 65 and older in the period running from 1 January 1999 to 31 December 2003. The OAS database used for this study reflects over 19 million life-years of exposure and about 860,000 deaths. The volume of data permits the study of the level of mortality experienced at the advanced ages with more accuracy and reliability as compared to other sources of information.

The mortality experience of OAS program beneficiaries is first evaluated on an overall basis and then by a classification of subgroups that takes into account place of birth, the type and amount of OAS benefit paid over the experience period for each individual. It is possible to distinguish those beneficiaries with high incomes as their level of basic OAS pension received is reduced through a provision of the *Income Tax Act* often referred to as the “clawback provision”. Similarly, it is possible to distinguish beneficiaries with low incomes as their basic OAS pension paid is increased by the Guaranteed Income Supplement (GIS) by different amounts depending on whether they had little or no income. The mortality experience of the OAS subgroup that resides in Canada less Québec is also analyzed, specifically between those receiving a Canada Pension Plan (CPP) retirement benefit and those not receiving the benefit.

As the 2000-2002 Life Tables for Canada (LTC) were not yet available at the time of this study, the OAS mortality experience was compared to a benchmark mortality table that was derived by projecting the 1995-1997 LTC mortality tables to the year 2001 based on mortality improvement rates experienced between 1996 and 2001. The life expectancies at age 65 resulting from the projected 1995-1997 LTC compare well with figures published by Statistic Canada for the year 2001. This benchmark mortality table is also the starting point for the mortality projections of the 7<sup>th</sup> OAS Actuarial Report on the Old Age Security Program as at 31 December 2003 (“7<sup>th</sup> OAS Report”).

The OCA will use the results of this study to assess the mortality of the overall Canadian population and the CPP and OAS beneficiaries when producing its next triennial actuarial reports on the CPP and OAS.

### B. Scope

Section II presents an overview of historical Canadian population trends as presented in the 7<sup>th</sup> OAS Report. Section III presents a summary of the data and methodology used to determine the mortality rates experienced by OAS beneficiaries over the period 1999 to 2003. A detailed analysis of the results is then presented in Section IV. Section V presents life expectancies at age 65 while Section VI presents the mortality improvement rates for each subgroup of beneficiaries. The conclusions of the study follow in Section VII. Lastly, various appendices in Section VIII provide statistics and further details in respect of the methodology used, and list the references used and contributors to this study.

### C. Main Findings

- The oldest OAS male beneficiary in pay in 2003 is 110 years old and the oldest female beneficiary is 112 years old.
- The overall mortality of OAS beneficiaries in Canada is 7% higher for males and 6% higher for females relative to the 2001 mortality table used in the 7<sup>th</sup> OAS Actuarial Report. The mortality difference is especially higher for the 85 to 89 and 90 to 94 age groups for both sexes.
- Male OAS beneficiaries experience mortality rates that are 72% higher than for females at ages 65 to 69. The gap in mortality rates between males and females decline significantly by age. For ages 85 to 89, mortality rates for males are 42% higher than for females.
- Based on estimated OAS program mortality rates in the year 2001, life expectancies at age 65 for OAS beneficiaries are 16.6 years for males and 20.2 years for females. These are lower than the life expectancies calculated for the 7<sup>th</sup> OAS Actuarial Report by 0.5 year for males and 0.4 year for females.
- The life expectancies at age 65 for those who receive clawback-reduced OAS benefits because of high income are 19.5 years for males and 22.4 years for females. This group of high-income earners, which represents only 5% of all OAS beneficiaries, experiences significantly higher life expectancies compared to low-income earners who receive GIS benefits. The life expectancies at age 65 for GIS recipients are 15.0 years for males (i.e., 4.5 years lower) and 19.0 years for females (i.e., 3.4 years lower).
- A high level of income is a long-term predictor of lower levels of mortality, and conversely, a low level of income is a long-term predictor of higher levels of mortality. However, the difference in mortality, according to the level of income, decreases with advancing age.

### D. Other Findings

- OAS beneficiaries who are immigrants experience lower mortality than beneficiaries who were born in Canada. Consequently, OAS beneficiaries born outside of Canada have greater life expectancies at age 65 than those born in Canada. The differential for males is 1.6 years and for females, it is 1.2 years.
- The greater life expectancies of immigrants as well as their relative better health compared to those born in Canada may be explained by a “healthy immigrant effect”<sup>1</sup> resulting from several factors, including medical and employability screening prior to entry to Canada as well as cultural and lifestyle characteristics.

---

<sup>1</sup> Chen J., Wilkins R. and Ng E., *Health Expectancy by Immigrant Status, 1986 and 1991*. Health Reports, Winter 1996, Vol. 8, No. 3, Statistics Canada.

## **E. Conclusion**

The availability and quality of the administrative OAS beneficiaries database provide sufficient and reliable data upon which this study is based and allow an accurate measurement of the level and trend in mortality experienced by the oldest portion of the Canadian population. The study shows that the level of OAS mortality based on the year 2001 is higher than the projected mortality from the 1995-1997 Life Tables for Canada by about 7% for males and 6% for females.

In general, GIS recipients experience higher mortality and thus lower life expectancies relative to the overall OAS population. In comparison, those who receive clawback-reduced OAS benefits experience lower mortality and higher life expectancies. This may be explained by the association between high levels of income and improved health and quality of life.

## II. Canadian Population Trends

The significant improvement in life expectancy over the last 40 years for those above age 65 is an important cause of the aging of the Canadian population. While most of the increase in life expectancy is a consequence of the reduction in mortality prior to age 65, recent increases in life expectancy have been mainly due to a reduction in mortality at ages 65 and over. The Canadian population has also aged due to a significant drop in the total fertility rate since the late 1950s and the aging of the baby boom generation (those mainly born between the mid-1940s and mid-1960s). Chart 1 shows the importance of the impact of the baby boom generation on the population for years 1966, 2001 and 2030 as the bulk of the age structure moves up into the older ages over time.

**Chart 1 Age Structure of the Canadian Population**

The historical and projected evolution of the proportion of the population aged less than 65 and aged 65 and over is shown in Chart 2. In 2001, 11% of males and 14% of females in the population were aged 65 or older. By 2030, these proportions are expected to grow significantly to 22% and 24% for males and females, respectively.

**Chart 2 Distribution of the Canadian Population Below and Above Age 65**

The historical and projected annualized growth rate by age group of the Canadian population is shown in Chart 3. While as a whole, the growth of the Canadian population is slowing down, the age group of those aged 80 and over has been one of the fastest growing age groups and this trend is expected to continue. As the growth in the population at the advanced ages is expected to remain strong, an increasing number of people will reach age 100.

**Chart 3 Average Annual Growth of the Canadian Population by Age Group**

Life expectancy at age 65 provides a good measure of how long social security benefits will be paid for both sexes. As shown in Table 1, life expectancy at age 65 for males was 13.8 years in 1966 and increased to 17.1 years by 2001, representing a growth of 24%. For women, life expectancy at age 65 in 1966 was 16.8 years and increased to 20.6 years over the same period, representing a growth of 23%. For both sexes, life expectancy at age 65 has increased steadily over the period 1966 to 2001. It is interesting to note that the difference between female and male life expectancies at age 65 has narrowed from 4.3 years in 1986 to 3.5 years in 2001. This can be explained by the fact that mortality improvement rates of males aged 65 years and older have been significantly higher than for females of the same age over this period.

**Table 1 Evolution of Life Expectancy at Age 65**

<b>Year</b>	<b>Males</b>	<b>Females</b>	<b>Female-Male Differential</b>
<b>1966</b>	13.8	16.8	3.0
<b>1971</b>	13.9	17.5	3.7
<b>1976</b>	14.1	18.1	3.9
<b>1981</b>	14.6	18.9	4.2
<b>1986</b>	15.0	19.3	4.3
<b>1991</b>	15.7	19.9	4.2
<b>1996</b>	16.0	19.9	3.9
<b>2001</b>	17.1	20.6	3.5

The evolution of the Canadian population aged 65 and over has a direct impact on the OAS program since it provides a monthly basic OAS pension to all Canadians aged 65 and over who meet the residence and legal status requirements specified in the *Old Age Security Act*. According to the 7<sup>th</sup> OAS Report, the number of recipients of the basic OAS pension is expected to more than double from 4.0 million in 2003 to 8.9 million in 2030. The number of recipients of the GIS is expected to increase by 66%, growing from 1.5 million in 2003 to 2.4 million in 2030. The percentage increase in GIS recipients is less than that for basic OAS recipients due to the expected decline in the GIS recipient rates over the same period.

The projected population aged 65 and over is continuing to grow and influence the costs of social insurance programs like the OAS. It is thus critical to be able to measure as precisely as possible the mortality experience of this age group. There are many possibilities for the future evolution of mortality at older ages ranging from the theory of squaring of the survival curve (also called “mortality compression”) to the theory of steady progress (also called “mortality expansion”). A survival curve at age 65 shows the probability of a 65 year old reaching a given age.

Mortality compression at the older ages occurs if age-specific mortality declines over a widening range of older ages but meets natural limits for very advanced ages, assuming there is a limit to the maximum lifespan. This is consistent with the aging process being both continuous and accompanied by an increasing degree of frailty. Mortality compression is thus also consistent with exponential growth in mortality rates.

In the case of mortality expansion, the age at which natural limits occur could move upward; that is, the maximum age to which one could expect to live would continuously increase. Consequently, all age groups would continue to experience declining mortality. This is consistent with a logistic form of the mortality curve, which has a more gradual growth in mortality at the advanced ages.

This study of the mortality experience of OAS beneficiaries provides a measure of the historical level and trend in mortality experienced by the oldest group of the Canadian population and gives some indication as to which theory for the survival curve at the older ages may best apply.

### III. Data and Methodology

#### A. Data

The main source of data for this study was an administrative seriatim (i.e., by non-identifiable individual record) OAS beneficiary database that was provided by the Department of Human Resources and Social Development Canada (HRSDC), which is the administrator of the OAS program. The OAS database contains information on the amount of regular monthly benefits received by each OAS beneficiary along with the associated payment status (i.e., in pay or terminated) for all OAS beneficiaries at each 31 December for years 1999 to 2003 inclusively. Note that social insurance numbers are masked and it is impossible to identify an individual.

Data from the OAS database were tabulated by year, age at last birthday, sex, place of birth, and levels of income as determined from the type and amount of monthly benefits received. The amount of OAS basic pension paid to persons with high incomes is reduced through a provision of the *Income Tax Act* often referred to as the “clawback provision”<sup>1</sup> while those who are entitled to 100% of the maximum GIS benefit in addition to the OAS basic pension have no or very low income<sup>2</sup>. The mortality experience of OAS beneficiaries is first estimated on an overall basis and then by subgroups that take into account the type of benefit received over the period of the study. The subgroups considered were as follows:

1. **Basic OAS with Clawback:** OAS beneficiaries entitled to a reduced basic OAS pension because of the application of the clawback provision.
2. **Basic OAS without Clawback:** OAS beneficiaries not affected by the application of the clawback provision.
3. **Basic OAS with GIS:** OAS beneficiaries entitled to both a basic OAS pension and income-tested GIS benefit.
4. **Basic OAS without GIS:** OAS beneficiaries not entitled to the GIS benefit.
5. **Basic OAS without Clawback or GIS:** OAS beneficiaries entitled only to a basic OAS pension without clawback or income-tested GIS benefits.

These subgroups comprise different sets of all OAS beneficiaries. Some subgroups include all or part of others. For instance, subgroup 2 is composed of subgroups 3 and 5. Each subgroup, however, was considered important for its own respective characteristics and as such was included in the study.

A second database used for this study was the administrative seriatim Canada Pension Plan (CPP) retirement beneficiary database that was also provided by HRSDC. This database allowed the identification of those OAS beneficiaries who were also in receipt of a CPP retirement benefit. In the absence of an equivalent database for the Québec

<sup>1</sup> The clawback reduction in the OAS basic pension in a given year is based on a beneficiary’s net income and a certain threshold in the previous year. For each dollar of net income above the threshold, the OAS basic pension is reduced by 15%. In 2005, the threshold was \$60,806 and the pension is completely clawed back at a net income level at or above \$98,850.

<sup>2</sup> The level of income used to determine the level of GIS entitlement excludes any benefits received from the OAS program, as well as Employment Insurance premiums, CPP/QPP contributions, a portion of employment income, and various other types of income.

Pension Plan (QPP), it was not possible to identify OAS beneficiaries in receipt of QPP retirement benefits. As a consequence, the study further compares the mortality experience of OAS beneficiaries living in Québec and those living outside of Québec. For OAS beneficiaries residing in Canada excluding Québec, mortality experience was analyzed based on whether or not a CPP retirement benefit was payable.

For all OAS beneficiaries who were reported as being age 110 or older, a validation of date of birth and date of death information was performed by HRSDC, which improved the accuracy of the data for the advanced ages.

For those beneficiaries reported as being between the ages of 100 and 109, a random sample of records was validated by HRSDC. It was found that about 3% of the sample required data corrections. As such, it was estimated that the number of records for this age group requiring corrections would have a minimal impact on the resulting mortality rates.

The CPP retirement beneficiary file was also used as an independent source of information to validate the data consistency of the OAS beneficiary database. For instance, from the two files it was possible to:

- exclude records present in both files that were inconsistent with respect to sex, date of birth, and date of death.
- generate a deemed date of death for records in the OAS database that were missing a date of death but where the payment status information in the OAS database had strongly suggested the occurrence of death based on a statistical analysis of records in both the CPP and OAS files with the same characteristics.

Table 2 shows data validation statistics resulting from the merging of the OAS and CPP databases.

**Table 2 Data Validation Statistics**

	<b>In Both OAS and CPP Retirement Databases*</b>	<b>OAS Database Only**</b>	<b>Total OAS Database</b>
<b>Number of records prior to the following exclusions:</b>	<b>3,237,862</b>	<b>2,118,992</b>	<b>5,356,854</b>
<b>Exclusions:</b>			
OAS effective year after 2003 (post-study period)	165,893	98,023	263,916

\* Excludes early retirement CPP beneficiaries under the age of 65 on 31 December 2003.

\*\* Includes OAS beneficiaries aged 65 and over who were either Québec residents (including QPP retirement beneficiaries) or Canada less Québec residents who were not receiving a CPP retirement benefit.

\*\*\* Pending OAS accounts were not in pay during the study period.

## B. Methodology Overview

This section provides a general overview of the methodology used in the development of the mortality rates of Canadian resident OAS beneficiaries who were aged 65 and older during the period 1 January 1999 to 31 December 2003.

The final mortality rates were based on the year 2001 and were derived using the following four-step process:

### 1. Production of Annual Crude Mortality Rates

The crude mortality rate for a given age at last birthday in any given calendar year is the probability that a person at that age on 1 January dies by 31 December of that year. Crude mortality rates are usually calculated by simply dividing the relevant number of deaths by the number of exposures, where the number of exposures is the number of lives at the beginning of the year or period and so exposed to the probability of dying over that period. There exist various methods to determine crude mortality rates. For this study, annual crude mortality rates were determined using the Product-Limit Estimator (PLE) method, also known as the Kaplan-Meier Product-Limit Estimator method. Further details of this and other methods are provided in Appendix B. The results of various death and exposure tabulations are given in section IV.A.

## **2. Production of 2001 Base Year Crude Mortality Rates**

The 2001 base year crude mortality rates were derived from annual crude mortality rates over the period 1999 to 2003. The methodology used to derive the year 2001 rates was based on the analysis of four different methods for their soundness and ability to produce mortality rates adjusted for mortality improvements. The methodology is described in detail in Appendix C.

## **3. Production of 2001 Base Year Graduated Mortality Rates**

The 2001 base year crude mortality rates were graduated to reflect a compromise between smoothness and fit. A Whittaker-Henderson Type B graduation method was used to produce the graduated rates up to age 100, which was the highest age showing statistically credible mortality rates.

## **4. Extension of Mortality Rates to Age 120**

Two methods were used to extend the graduated rates beyond age 100.

The first method was to extend a least squares linear regression of the function  $\ln(q_x/q_{x-1})$  on age, where  $q_x$  was the 2001 base year graduated mortality rates for males and females at age  $x$ . The function was almost linear between the ages 90 and 100 for each sex. Under this method, which assumes a gradual growth in mortality rates at the advanced ages, the ultimate mortality rates reached at age 120 were about 0.62 for males and 0.54 for females. In comparison, the 2001 benchmark mortality rates were about 0.82 and 0.70 at age 119 for males and females, respectively. The mortality rates for the different subgroups studied were set to converge to those of the overall population of OAS beneficiaries at advanced ages.

The second method of extension of mortality rates used the same mortality rates as derived from the first method up until age 110. From age 110, mortality rates were then projected using an exponential growth model to eventually reach a mortality rate of 1 by age 120.

The mortality rates obtained from the first method were preferred for this study, as they better reflected the experience and trend in mortality rates at the advanced ages for both sexes.

## IV. Results

### A. Overall OAS Program Mortality

As the OAS program provides pensions to almost all Canadians aged 65 and over, the availability of an administrative OAS database allows us to measure more accurately the level and trend in mortality experienced by the oldest portion of the Canadian population.

#### 1. Deaths

The basic element in the estimation of the OAS program mortality rates is to count the number of deaths by calendar year, age and sex. As only the year and month of birth were available from the OAS database, the day of birth for each OAS beneficiary was assumed to be in the middle of that month. This in turn divided the year into 24 subintervals, each beginning either on the 1<sup>st</sup> or middle of the month. Similarly, as only the year and month of death were available, the day of death was assumed to be in the middle of that month.

Special adjustments were made in the cases where both the months of birth and death were the same. For these cases, a uniform distribution of births and deaths was assumed so that, on average, half the deaths occur before the date of death and the other half occur after. This results in about half the number of deaths occurring at the unadjusted age at death and the other half at an age one year younger.

Table 3 presents the number of deaths from the overall OAS program at ages 65 and over by age group and sex. Of the 868,086 observed deaths from the OAS database, there were 7,824 (83% being females) alleged to have died as centenarians, and among those, 29 (97% being females) died as supercentenarians (aged 110 or older). Table 23 and Table 24 in Appendix A show detailed statistics on the number of male and female deaths by individual age for various subgroups of beneficiaries.

**Table 3 OAS Beneficiary Deaths (1999-2003)**

Age Group	OAS Program		
	Males	Females	Both Sexes
<b>65-69</b>	53,665	33,482	87,147
<b>70-74</b>	75,473	51,001	126,474
<b>75-79</b>	90,793	74,684	165,477
<b>80-84</b>	86,183	90,856	177,038
<b>85-89</b>	66,868	97,019	163,886
<b>90-94</b>	32,744	69,564	102,308
<b>95-99</b>	9,144	28,790	37,934
<b>100-104</b>	1,225	5,974	7,199
<b>105-109</b>	84	512	596
<b>110+</b>	1	28	29
<b>Total</b>	416,179	451,907	868,086

Table 4 shows a comparison by age group and sex of the number of OAS beneficiary deaths to the number of deaths as reported by Statistics Canada (official vital statistics) over the period 1999 to 2003. For ages 65 to 69, the lower number of OAS deaths compared to that of the vital statistics may be explained by recipient rates for the OAS benefit being less than 100%. This may be explained by the fact that a portion of the population has still not applied for the OAS benefit by age 69 as they are not yet eligible or have elected not to receive OAS benefits. For ages 70 and above, the number of deaths from vital statistics was lower than that of OAS beneficiaries.

**Table 4 OAS Beneficiary Versus Vital Statistics Deaths (1999-2003)**

Age Group	Males			Females		
	OAS	Vital Statistics <sup>(*)</sup>	Ratio OAS to Vital Statistics	OAS	Vital Statistics <sup>(*)</sup>	Ratio OAS to Vital Statistics
65-69	53,665	54,191	99%	33,482	34,003	98%
70-74	75,473	74,822	101%	51,001	50,822	100%
75-79	90,793	89,767	101%	74,684	74,421	100%
80-84	86,183	85,144	101%	90,856	90,105	101%
85-89	66,868	66,292	101%	97,019	96,310	101%
90+	43,198	43,113	100%	104,868	104,163	101%
65+	416,179	413,329	101%	451,907	449,824	100%

(\*) The number of deaths for the period 1999 to 2002 is from official vital statistics from Statistics Canada, while the number of deaths for 2003 is derived from post-Census estimates of Statistics Canada.

## 2. Exposures

Exposures by calendar year, age and sex were derived using a seriatim approach. Exposures are interpreted as the number of life-years that were exposed to risk of death during the period examined.

The exposures were determined by an exact age method whereby, for each person, exposure was measured from the normal age at commencement of OAS benefits (65.04 years) to the time of death. The exposures were then tabulated by age and sex. The fractional years were determined by attained age at each birthday and at the end of each year of the study. Each half-month was given the same weight of one twenty-fourth of a year.

Exposures by age group and sex are shown in Table 5. As females live longer than males on average, the exposures for females are distributed more to the advanced ages. Tables 25, 26 and 27 in Appendix A present various detailed statistics related to exposures.

**Table 5 OAS Beneficiary Exposures (1999-2003)**

Age Group	Exposures		Distribution	
	Males	Females	Males	Females
<b>65-69</b>	2,613,513	2,808,490	32.2%	25.9%
<b>70-74</b>	2,262,297	2,652,654	27.9%	24.5%
<b>75-79</b>	1,663,584	2,309,706	20.5%	21.3%
<b>80-84</b>	963,117	1,615,836	11.9%	14.9%
<b>85-89</b>	451,368	949,856	5.6%	8.8%
<b>90-94</b>	140,566	393,925	1.7%	3.6%
<b>95-99</b>	25,720	100,691	0.3%	0.9%
<b>100-104</b>	2,567	14,155	0.0%	0.1%
<b>105-109</b>	135	925	0.0%	0.0%
<b>110+</b>	5	44	0.0%	0.0%
<b>65+</b>	8,122,873	10,846,282	100.0%	100.0%

The number of OAS beneficiaries as at December 31 of each of the years in the study period is shown in Table 6. The OAS program provides a payment in the month of death, which is reflected in the number of beneficiaries shown. Table 28 in Appendix A presents the number of OAS beneficiaries by individual age in pay as at December 31 over the study period. As at 31 December 2003 and verified by HRSDC, the oldest male beneficiary was age 110 and the oldest female beneficiary was age 112.

**Table 6 Number of OAS Beneficiaries in Pay (1999-2003)**

As at 31 <sup>st</sup> December	1999		2000		2001		2002		2003	
	Age Group	Males	Females	Males	Females	Males	Females	Males	Females	Males
<b>65-69</b>	520,542	560,886	519,242	560,013	520,480	560,246	521,124	561,636	523,424	564,145

### 3. Mortality Rates

#### a) 2001 Base Year Crude Mortality Rates

The resulting 2001 base year crude mortality rates by age and sex are presented in Table 7. The ratio of male to female rates is an indicator of the average shorter lifetimes of males compared to females. However, although males experience a higher level of mortality than females, the relative gap between the two sexes narrows as mortality converges with advancing ages as can be seen by the falling male/female mortality ratio.

**Table 7 OAS Beneficiary Crude Mortality Rates (2001)**

Age Group	Males	Females	Ratio Males to Females
65-69	0.0203	0.0118	1.71
70-74	0.0328	0.0190	1.72
75-79	0.0532	0.0318	1.67
80-84	0.0858	0.0548	1.57
85-89	0.1379	0.0971	1.42
90-94	0.2082	0.1620	1.28
95-99	0.2990	0.2488	1.20
100*	0.3427	0.3252	1.05

\* Age 100 was the highest age with statistically credible crude mortality rates.

The progression of the 2001 base year crude mortality rates by age and for each sex is displayed in Chart 4. Males experience a higher level of mortality than females except at the very advanced ages.

**Chart 4 OAS Beneficiary Crude Mortality Rates (2001)**

b) 2001 Base Year Graduated Mortality Rates

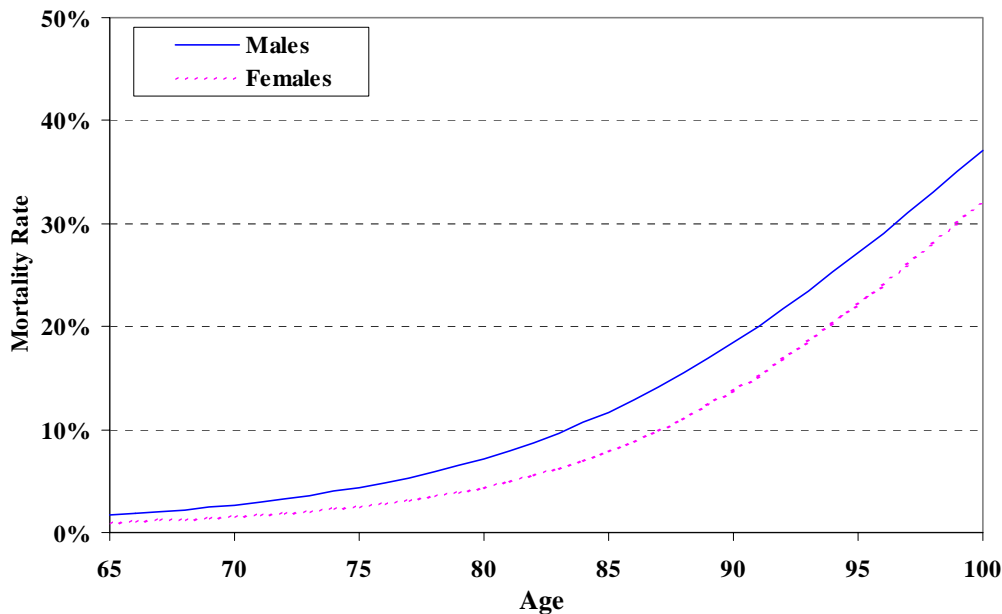

The graduated mortality rates by age and sex and the corresponding ratio of male to female rates are presented in Table 8. As noted for the crude mortality rates, males experience a higher level of mortality than females, but the relative gap between the sexes decreases with advancing ages as can be seen by the falling male/female graduated mortality ratio.

The crude mortality rates were graduated up to age 100, which was the highest age with statistically credible rates. The graduated rates from age 100 were then extended to age 120, which was considered to be the maximum attainable lifespan. The projection of the rates to age 120 is discussed further in the following subsection. Chart 5 below shows the graduated mortality rates to age 100 for each sex.

**Table 8 OAS Beneficiary Graduated Mortality Rates (2001)**

Age Group	Males	Females	Ratio Males to Females
65-69	0.0203	0.0118	1.72
70-74	0.0328	0.0190	1.73
75-79	0.0532	0.0318	1.67
80-84	0.0858	0.0549	1.56
85-89	0.1377	0.0970	1.42
90-94	0.2086	0.1623	1.29
95-99	0.2957	0.2482	1.19
100	0.3711	0.3211	1.16

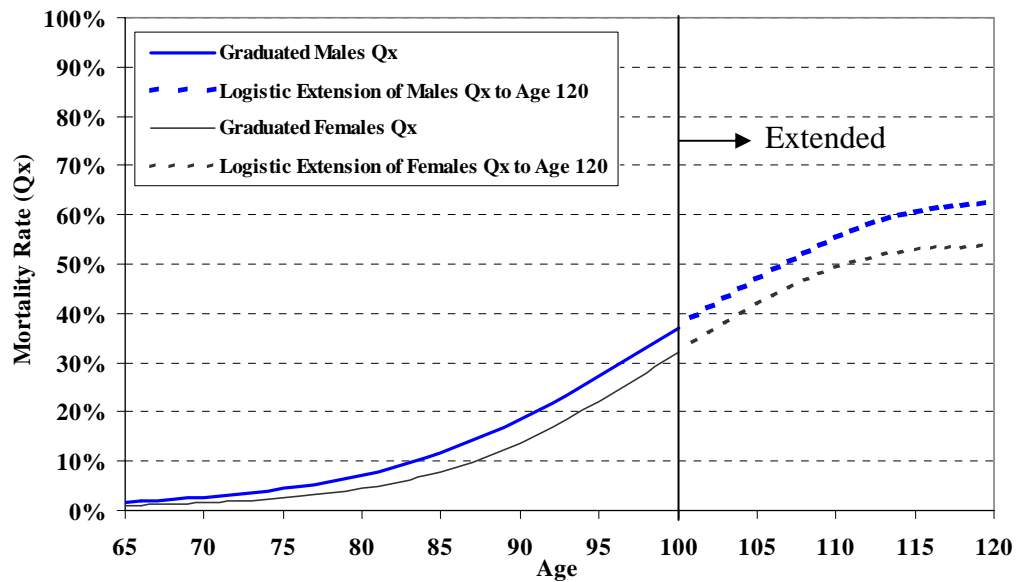

**Chart 5 OAS Beneficiary Graduated Mortality Rates (2001)**

c) Extension of Graduated Mortality Rates to Age 120

The graduated mortality rates were extended to age 120 using a logistic<sup>1</sup> function since it reflected rising mortality at diminishing rates as seen at the advanced ages. An exponential function was also considered but not used, as explained further in Appendix D. The graduated and extended rates for both sexes are shown below in Chart 6.

**Chart 6 OAS Beneficiary Mortality Rates with Extensions to Age 120 (2001)**

<sup>1</sup> A logistic curve is an S-shaped curve which models the growth of some population over time. It is characterized by low initial growth, followed by a period of rapid or exponential growth, and then ending with a gradual slowing down to an equilibrium level as the population matures.

## B. Mortality Comparisons

In this section, mortality rates of different groups are compared by way of ratios of the rates by age and sex. A comparison is first made between the overall mortality of OAS beneficiaries and a benchmark mortality table. A comparison is then made for OAS beneficiaries between those born in Canada and immigrants. A third comparison is made between various subgroups of the OAS beneficiaries by type of benefits received. Lastly, comparisons are made for the population of Canada less Québec with respect to the overall mortality of the beneficiaries and between those in receipt of CPP retirement benefits and those not in receipt of the benefits.

### 1. Comparison with Benchmark Mortality

Since OAS program beneficiaries represent a large portion of the older Canadian population, the base year 2001 OAS mortality rates were compared to a benchmark mortality table for Canada for the year 2001. The benchmark mortality table was derived from the Life Tables for Canada for years 1995 to 1997, projected to the year 2001 based on mortality improvement rates from 1996. This benchmark corresponds to the starting point of the mortality projections in the 7<sup>th</sup> OAS Report.

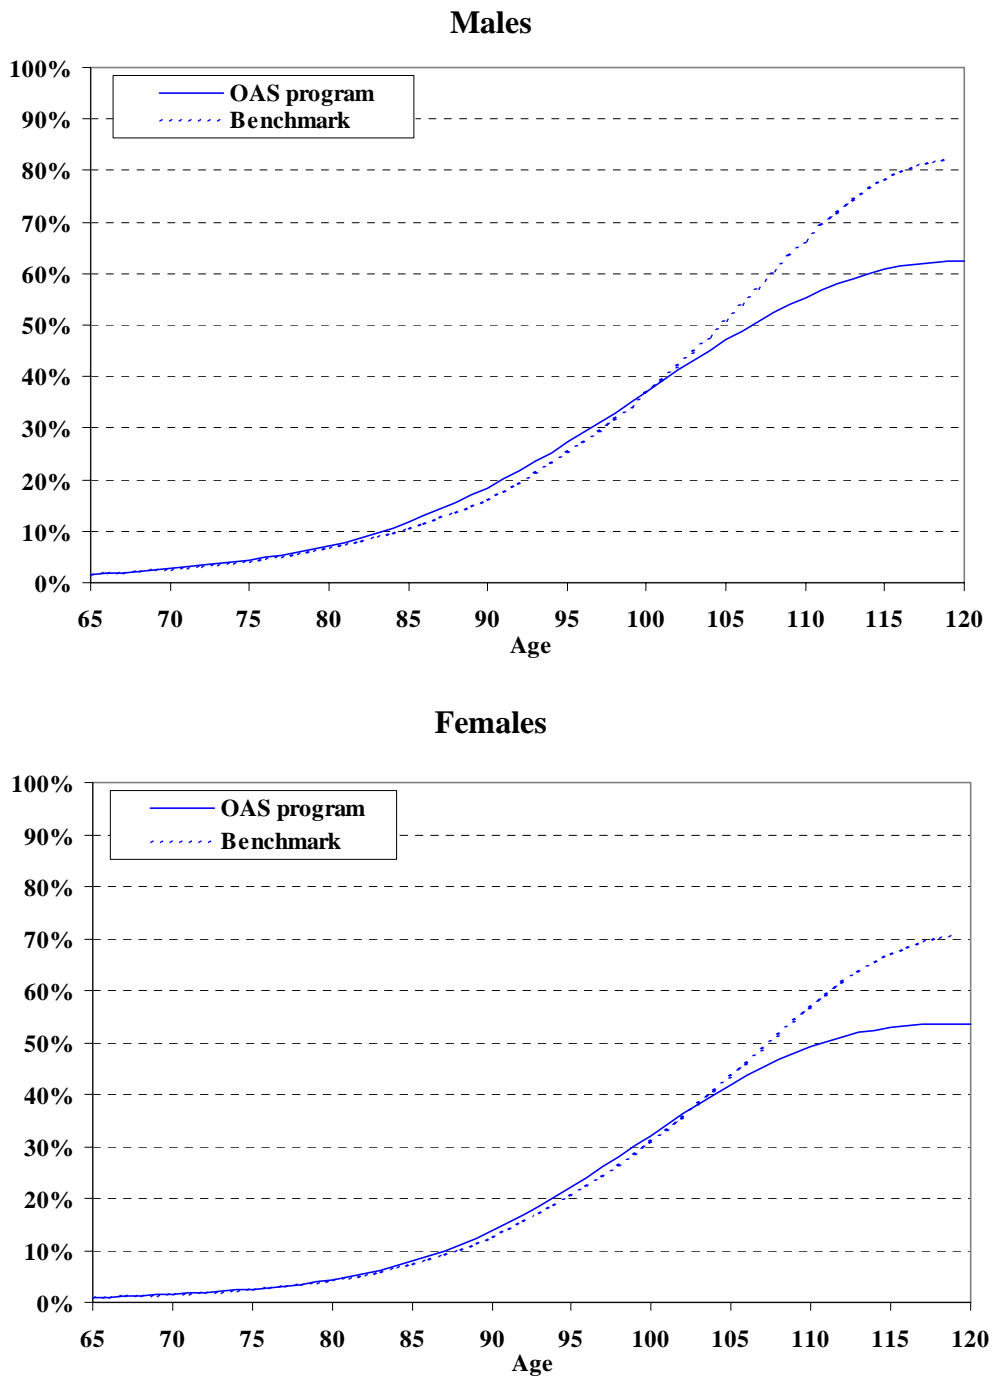

Male and female OAS beneficiaries experienced higher mortality in relation to the benchmark mortality, as shown in Table 9. The ratio of OAS mortality rates to benchmark rates is generally higher for males than for females. The highest mortality ratios occur for males in the age groups between 85 and 94. Mortality rates and other life table statistics for OAS beneficiaries are provided in Table 29 of Appendix A.

**Table 9 OAS Beneficiary Versus Benchmark Mortality Rates (2001)**

Age Group	Males			Females		
	OAS	Benchmark	Ratio OAS to Benchmark	OAS	Benchmark	Ratio OAS to Benchmark
<b>65-69</b>	0.0203	0.0197	1.03	0.0118	0.0113	1.04
<b>70-74</b>	0.0328	0.0314	1.04	0.0190	0.0181	1.05
<b>75-79</b>	0.0532	0.0499	1.07	0.0318	0.0306	1.04
<b>80-84</b>	0.0858	0.0793	1.08	0.0549	0.0526	1.04
<b>85-89</b>	0.1377	0.1231	1.12	0.0970	0.0905	1.07
<b>90-94</b>	0.2086	0.1858	1.12	0.1623	0.1501	1.08
<b>95-99</b>	0.2957	0.2799	1.06	0.2482	0.2324	1.07
<b>100+</b>	0.3977	0.4045	0.98	0.3500	0.3457	1.01
<b>65+</b>	0.0491	0.0458	1.07	0.0398	0.0377	1.06

The graphs of OAS and benchmark mortality rates for year 2001 are shown below in Chart 7. OAS mortality rates for females are relatively closer to their respective benchmark than for males. For both sexes, however, the OAS mortality curves are flatter than the benchmarks after age 80, and the difference is pronounced after age 100 when OAS mortality falls below the benchmarks.

**Chart 7 OAS Beneficiary Versus Benchmark Mortality Rates (2001)**

## 2. Comparison Between Those Born in Canada and Immigrants

Immigration to Canada has historically been volatile. However, historical levels have been relatively high compared to the general population. Moreover, as the total fertility rate has fallen significantly since the late 1950s to below replacement level, immigration has composed an increasing portion of the growth of the Canadian population. The number of life-years of exposure by place of birth is shown in Table 10. The proportion of those born outside Canada increases with age group.

**Table 10 OAS Beneficiary Exposures by Place of Birth (1999-2003)**

Age Group	Males				Females			
	Born in Canada	Born Outside of Canada	OAS Beneficiaries	Proportion Born Outside of Canada	Born in Canada	Born Outside of Canada	OAS Beneficiaries	Proportion Born Outside of Canada
65-69	1,883,166	730,347	2,613,513	28%	2,089,067	719,423	2,808,490	26%
70-74	1,613,425	648,872	2,262,297	29%	1,952,504	700,149	2,652,653	26%
75-79	1,176,255	487,330	1,663,585	29%	1,668,326	641,381	2,309,707	28%
80-84	714,208	248,909	963,117	26%	1,239,604	376,231	1,615,835	23%
85-89	326,751	124,617	451,368	28%	715,128	234,729	949,857	25%
90-94	71,019	69,547	140,566	49%	207,441	186,484	393,925	47%
95-99	8,965	16,755	25,720	65%	37,396	63,295	100,691	63%
100+	871	1,836	2,707	68%	5,373	9,751	15,124	64%
65+	5,794,660	2,328,213	8,122,873	29%	7,914,840	2,931,442	10,846,282	27%

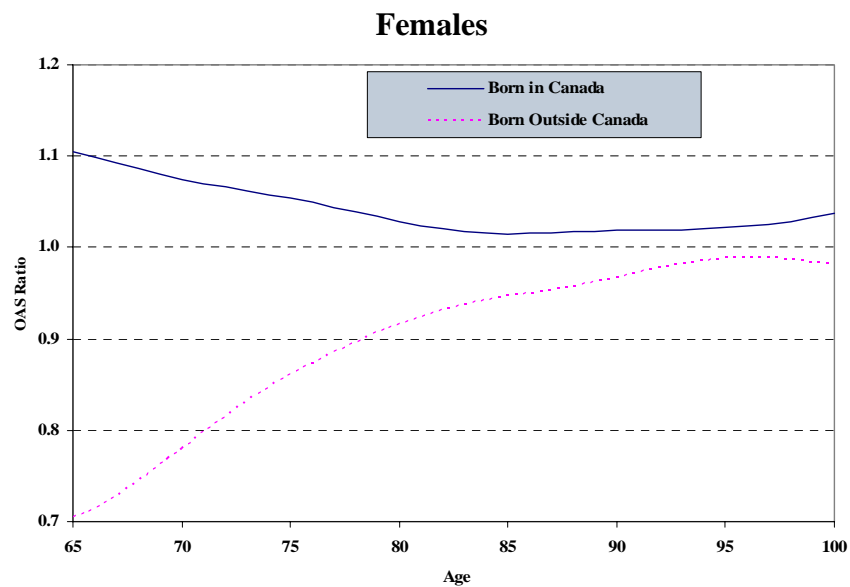

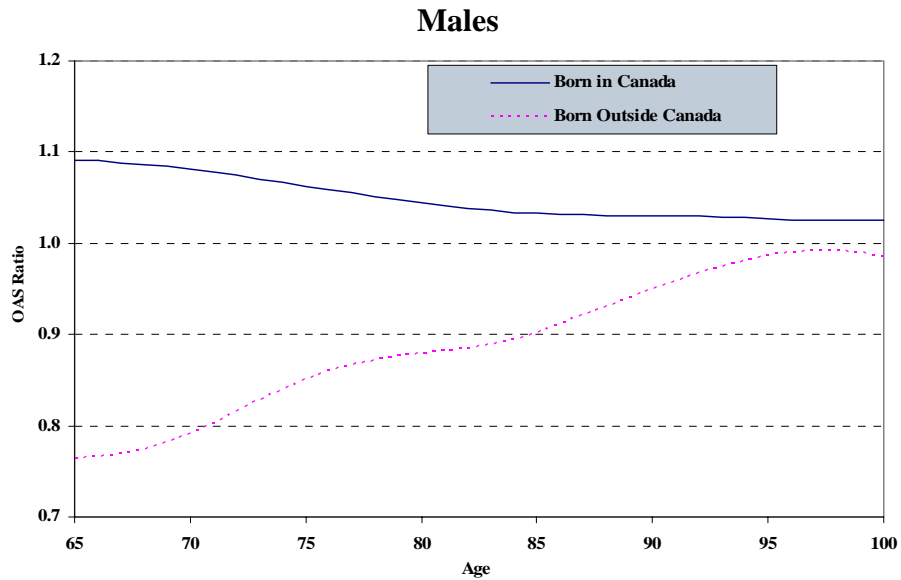

As presented in Table 11 and illustrated in Chart 8, immigrants experience lower mortality than those born in Canada. As such, immigrants have contributed to increasing life expectancies in Canada. The greater life expectancies of immigrants as well as their relative better health compared to those born in Canada may be explained by a “healthy immigrant effect” as referred to by Chen, Wilkins and Ng<sup>1</sup>. They describe this effect as resulting from several factors. First, people in poor health are less likely to migrate to another country. In addition, all potential immigrants to Canada are subject to medical screening. Moreover, immigrants to Canada are partially selected on the basis of employability, which would imply a certain status of health. As new immigrants tend to be healthy, they could experience greater life expectancies than those who had immigrated years earlier. Lastly, cultural and lifestyle characteristics of immigrants may also contribute to their relative better health and increased longevity. Table 31 in Appendix A provides the mortality ratios of OAS beneficiaries by individual age and place of birth.

<sup>1</sup> Chen J., Wilkins R. and Ng E., *Health Expectancy by Immigrant Status, 1986 and 1991*. Health Reports, Winter 1996, Vol. 8, No. 3, Statistics Canada.

**Chart 8 OAS Beneficiary Mortality Ratios by Place of Birth (2001)**

### 3. Comparison by Type of Benefit

#### a) OAS, GIS, and the Clawback

The age and sex structure of the amount of exposures by type of OAS benefit received over the period from 1999 to 2003 is displayed in Chart 9. The total exposures for females exceed that for males, and this is especially evident at the older ages. This difference is indicative of life expectancies for females being greater than for males.

Consistent with the fact that males generally have higher levels of income than females, the proportion of life-years during which males received clawback-reduced OAS benefits was higher than the corresponding proportion for females. For instance, the clawback was applied to 8% of exposures for males compared to 2% for females at age 65. Likewise, the proportion of life-years during which females received GIS benefits was higher than the corresponding proportion for males. The GIS was payable for 30% of exposures for females compared to 27% for males at age 65.

A higher proportion of the exposures was subject to the basic OAS pension only at age 65 compared to other ages. This may be indicative of the approximate one-year lag that exists in the OAS program to recognize those who would be affected by the clawback or entitled to the GIS.

**Chart 9 Structure of OAS Beneficiary Exposures by Type of Benefit (1999-2003)**

Note that the exposure at age 65 in Chart 9 has been adjusted upward to take into account that OAS entitlement occurs at age 65.04 on an exact age basis. As such, the exposure at age 65 is missing 1/24<sup>th</sup> of a year relative to the other ages.

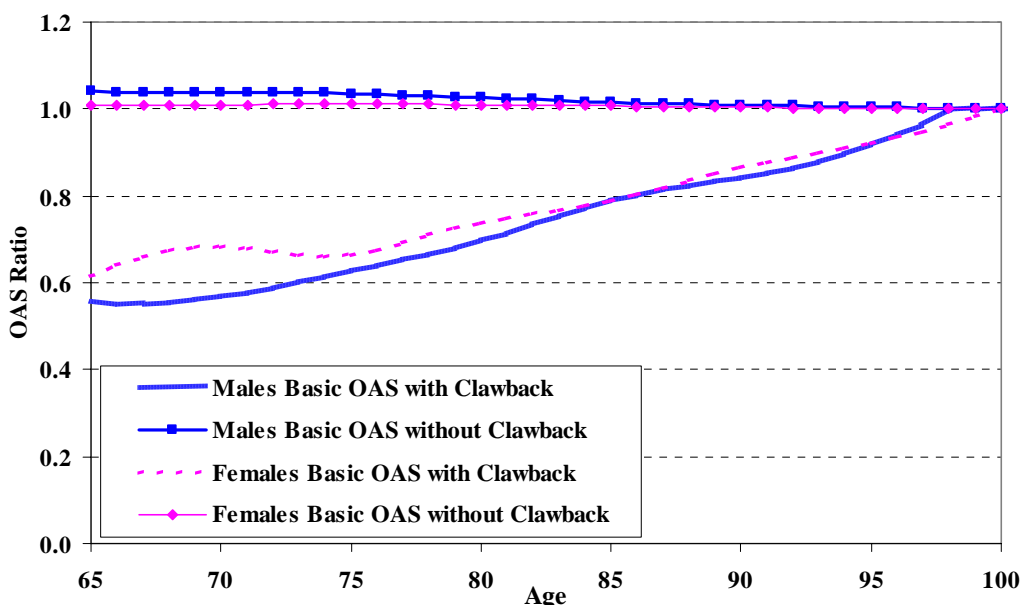

b) OAS with and without the Clawback

A comparison of the mortality rates between those who receive the basic OAS pension subject to the clawback, those not subject to the clawback, and all OAS beneficiaries is shown in Table 12 and Chart 10. Although they represent a small percentage of OAS beneficiaries, those who had their OAS benefits reduced by the clawback because of high income experienced significantly lower levels of mortality. Males experienced a wider range in mortality ratios than females. For example, males with clawback-reduced pensions experienced a mortality ratio of 0.55 compared to 0.66 for females for the age group 65 to 69. The corresponding mortality ratios for those not affected by the clawback provision are 1.04 for males and 1.01 for females. For both sexes, the mortality ratios converge to 1.0 as age increases. Table 32 in Appendix A provides mortality ratios by individual age and type of benefit.

**Table 12 Mortality Rates of OAS Beneficiaries by Application of the Clawback (2001)**

Age Group	Males					Females				
	Basic OAS with Clawback	Ratio OAS with Clawback to Overall OAS	Basic OAS without Clawback	Ratio OAS without Clawback to Overall OAS	Overall OAS	Basic OAS with Clawback	Ratio OAS with Clawback to Overall OAS	Basic OAS without Clawback	Ratio OAS without Clawback to Overall OAS	Overall OAS
65-69	0.0113	0.55	0.0211	1.04	0.0203	0.0078	0.66	0.0119	1.01	0.0118

**Chart 10 Mortality Ratios of OAS Beneficiaries by Application of the Clawback (2001)**

c) OAS without the GIS

A comparison of the mortality rates between those who receive the basic OAS pension with no GIS and all OAS beneficiaries is shown in Table 13 and Chart 11. Those beneficiaries who do not receive the GIS experience lower mortality compared to all OAS beneficiaries collectively. However, the subgroup rates approach the overall level as age increases, as seen by the increasing mortality ratios for both males and females.

**Table 13 Mortality Rates of OAS Beneficiaries Not Receiving the GIS (2001)**

Age Group	Males			Females		
	Basic OAS without GIS	Overall OAS	Ratio OAS without GIS to Overall OAS	Basic OAS without GIS	Overall OAS	Ratio OAS without GIS to Overall OAS

**Chart 11 Mortality Ratios of OAS Beneficiaries Not Receiving the GIS (2001)**

d) OAS with the GIS

The proportion of those OAS beneficiaries who were receiving the GIS benefit at the time of death generally increases with age as shown in Table 14. This is explained by the general trend that as older ages are reached net income tends to decrease, which leads to an increased likelihood of receiving the GIS.

The proportion of male OAS beneficiaries who were receiving the GIS benefit at the time of death increases overall from 40% for those in the age group 65 to 69 to 64% for those aged 100 and over. For females, the corresponding proportion increases from 45% to 74% over the same age range.

**Table 14 OAS and GIS Beneficiary Deaths (1999-2003)**

Age Group	Males			Females		
	Basic OAS with GIS	OAS Beneficiaries	Proportion OAS with GIS	Basic OAS with GIS	OAS Beneficiaries	Proportion OAS with GIS
65-69	21,677	53,665	40%	14,917	33,482	45%
70-74	28,606	75,473	38%	23,959	51,001	47%
75-79	31,993	90,793	35%	37,012	74,684	50%
80-84	32,213	86,183	37%	49,697	90,856	55%
85-89	28,045	66,868	42%	58,364	97,019	60%
90-94	16,209	32,744	50%	45,344	69,564	65%
95-99	5,188	9,144	57%	20,103	28,790	70%
100+	843	1,310	64%	4,849	6,514	74%
65+	164,773	416,179	40%	254,243	451,907	56%

The number of life-years of exposure for those receiving the GIS benefit in comparison to the overall amount of exposure for OAS beneficiaries is shown in Table 15. The proportion of exposures for female GIS recipients is significantly greater than that for males at all age groups, especially at and above age 70. This is due to women receiving less income than men and can be linked to the historically lower participation of women in the workforce. However, labour force participation rates for females have significantly increased recently and it is projected that the male-female participation gap will further narrow in the long term.

For males, the proportion of exposures for GIS recipients remains steady at 29% for age groups between 65 and 79 and then increases to 64% for those aged 100 and over. For females, the corresponding proportion increases through all age groups, from 32% for those aged 65 to 69 to 73% for those aged 100 and over.

For both sexes in the age group 65 to 69, the proportion of exposures for GIS recipients is significantly less than the proportion of deaths which reflects the higher level of mortality of GIS recipients for that age group. The difference in the proportions declines as age increases. For those aged 100 and older, exposure and death proportions are close to equal.

**Table 15 OAS and GIS Beneficiary Exposures (1999-2003)**

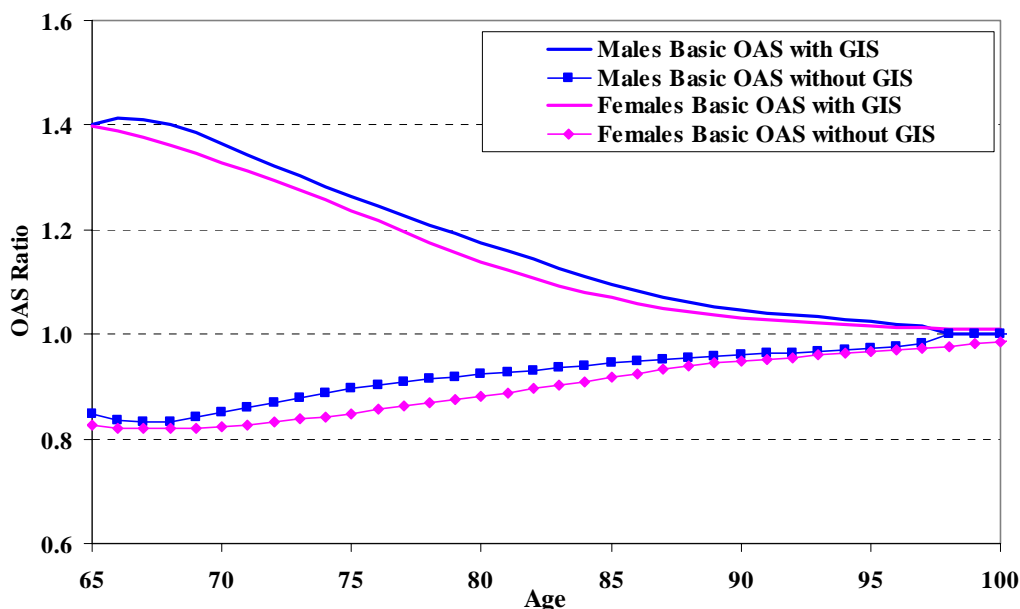

Age Group	Males			Females

<b>65+</b>	2,432,335	8,122,873	30%	4,469,816	10,846,282	41%

The mortality rates and mortality ratios of those who receive the GIS benefit are shown in Table 16 and Chart 12. For each sex, mortality ratios decrease and converge to the overall OAS program mortality at the advanced ages. Mortality ratios for those not in receipt of the GIS are also shown in Chart 12 for comparison.

**Chart 12 Mortality Ratios of OAS Beneficiaries by Receipt of the GIS (2001)**

**4. Others**

a) Canada less Québec and Québec Residents

Male OAS beneficiaries residing in the region of Canada less Québec experience lower mortality than OAS male beneficiaries collectively, while those males residing in Québec experience higher mortality. In comparison, female OAS beneficiaries residing in Canada less Québec and in Québec experience very similar mortality to all female OAS beneficiaries. These results are shown in Table 17 and Chart 13.

**Table 17 OAS Beneficiary Mortality Rates by Place of Residence (2001)**

**Chart 13 OAS Beneficiary Mortality Ratios by Place of Residence (2001)**

b) Canada less Québec Residents with and without a CPP Retirement Benefit

For OAS beneficiaries residing in Canada less Québec and receiving a CPP retirement benefit, mortality ratios generally increase with age, except at the very advanced ages for both sexes (see Table 18 and Chart 14). Male mortality rates start below overall male OAS rates, but eventually exceed them, whereas female rates remain below their overall rates and show a greater relative increase.

For OAS beneficiaries residing in Canada less Québec and not receiving a CPP retirement benefit, mortality ratios generally decrease with age, especially for males. Female mortality rates for this group converge to overall OAS rates.

The ability to have been part of the labour force and to have contributed to the CPP is a significant predictor of mortality experience. Mortality rates and other life table statistics for OAS beneficiaries in receipt of the CPP retirement benefit are provided in Table 30 of Appendix A. Mortality ratios for Canada less Québec and for Québec residents by individual age are provided in Table 33 of the same appendix.

**Table 18 OAS Beneficiary Mortality Rates of Canada less Québec Residents by Receipt of a CPP Retirement Benefit (2001)**

**Chart 14 OAS Beneficiary Mortality Ratios of Canada less Québec Residents by Receipt of a CPP Retirement Benefit (2001)**

**Males**

**Females**

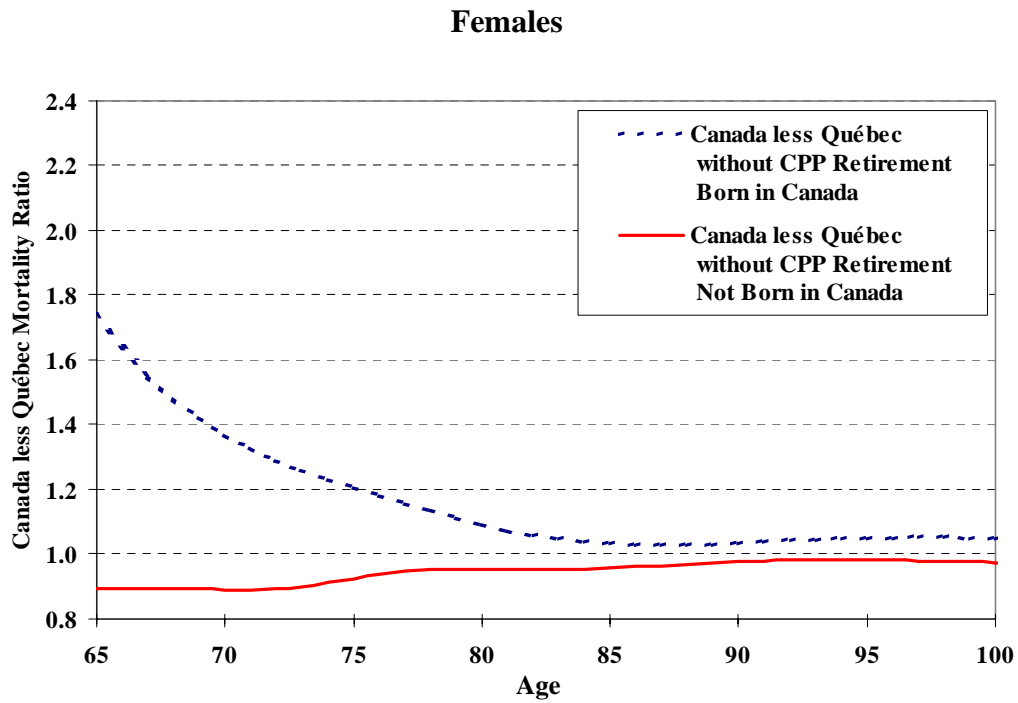

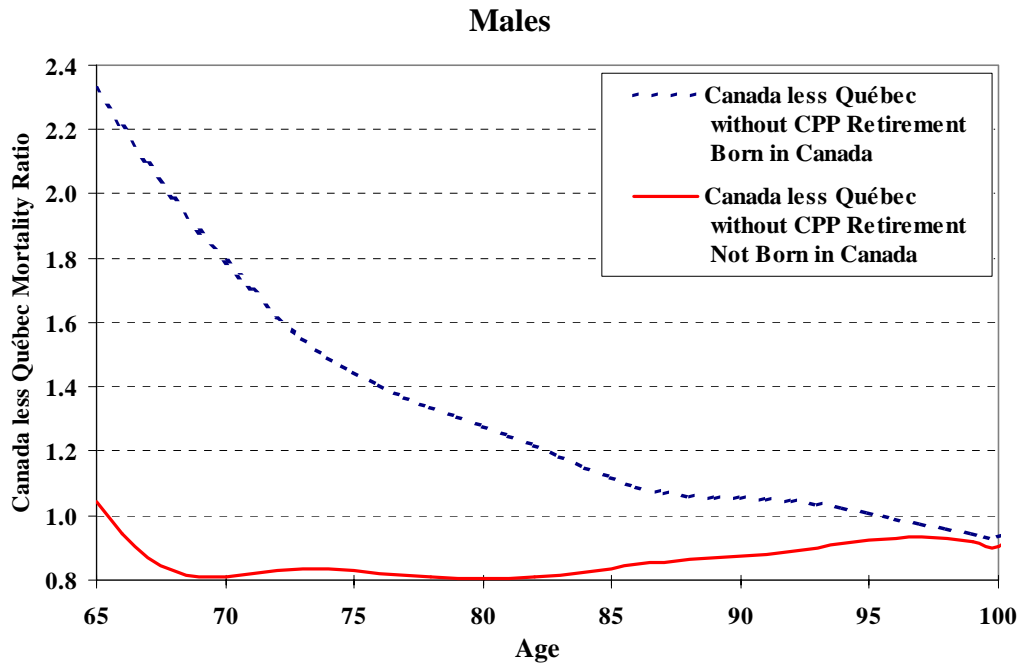

The mortality ratios for those OAS beneficiaries residing in Canada less Québec and not receiving a CPP retirement benefit may be further analyzed by place of birth as shown in Table 19 and Chart 15. The lower mortality experience of immigrants can most probably be linked to Canadian immigration screening policies, which include an assessment of medical conditions.

Those not born in Canada, or immigrants, experience much lower mortality compared to the overall OAS level for both sexes, and the converse is true for those born in Canada. In each case, the effect reduces as age increases. Moreover, male immigrants represent a higher proportion of those not entitled to CPP retirement benefits than for females, which explains the greater impact in the mortality ratios for males.

**Table 19 OAS Beneficiary Mortality Rates of Canada less Québec Residents without CPP Retirement Benefits by Place of Birth (2001)**

## V. Life Expectancies

A comparison of life expectancies at age 65 between the various subgroups and the benchmark population is shown below in Table 20. The life expectancies shown in Table 20 do not include future mortality improvements.

Overall, since the mortality of OAS beneficiaries is higher than that of the benchmark, life expectancies at age 65 are correspondingly lower. The differential in life expectancies at age 65 between the overall OAS program and the benchmark is larger for males (0.5 year) than for females (0.4 year).

Those OAS beneficiaries who were born outside of Canada have greater life expectancies than those born in Canada. The differential for males is 1.6 years and for females, it is 1.2 years. For those born in Canada, the gap between female and male life expectancies is 3.7 years which is higher than the corresponding differential of 3.3 years for immigrants.

An analysis of the differential in life expectancies at age 65 by type of OAS benefit shows that males experience a wider range in life expectancies at age 65 between the wealthier and poorer OAS beneficiaries. The differential in life expectancies at age 65 between those who received clawback-reduced OAS benefits and those who received basic OAS and GIS benefits is 4.5 years for males and 3.4 years for females.

The gap in life expectancies at age 65 between the two sexes decreases the higher the level of income, from 4.0 for those receiving the GIS to 2.9 for those affected by the clawback.

**Table 20 OAS Beneficiary Life Expectancies at Age 65 (2001)**

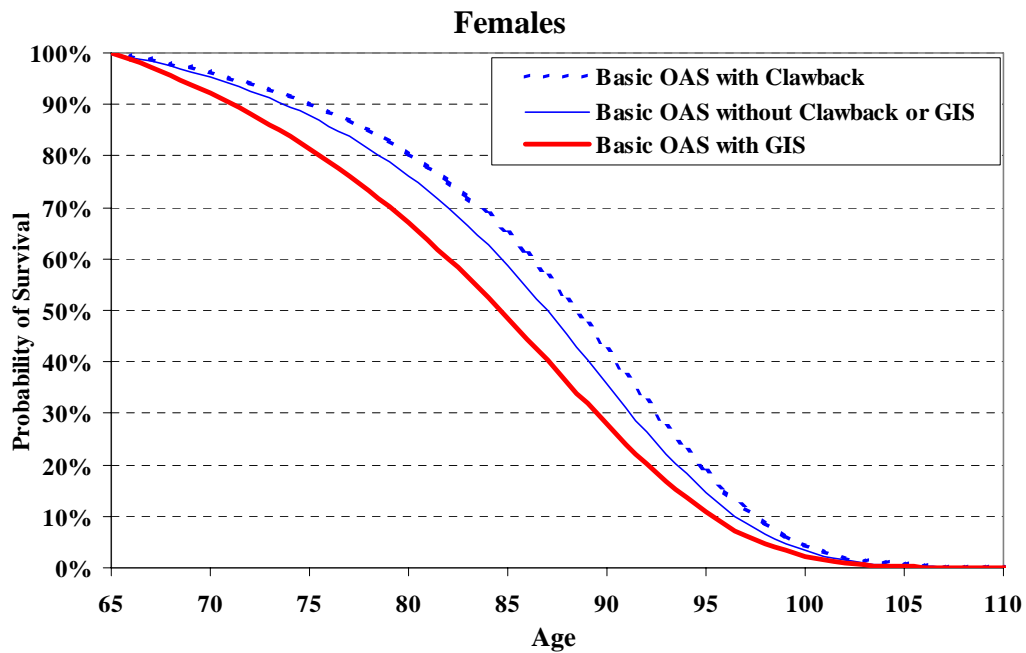

Type of Benefit	Males	Females	Female – Male Differential
OAS program	16.6	20.2	3.6
Benchmark	17.1	20.6	3.5
Differential between Benchmark & OAS program	0.5	0.4	
Born in Canada	16.2	19.9	3.7
Born outside of Canada (immigrants)	17.8	21.1	3.3
Differential between immigrants and born in Canada	1.6	1.2	
Basic OAS with GIS	15.0	19.0	4.0
Basic OAS without Clawback or GIS	17.2	21.1	3.9
Basic OAS with Clawback	19.5	22.4	2.9
Differential between OAS with Clawback and OAS with GIS	4.5	3.4	
Canada less Québec	16.8	20.2	3.4
Canada less Québec without CPP retirement benefit	15.4	19.5	4.1
Canada less Québec with CPP retirement benefit	16.8	20.5	3.7
Differential between Canada less Québec with and without CPP retirement benefit	1.4	1.0	

The probability of surviving from age 65 to a given age by type of benefit received is displayed by the survival curves for males and females in Chart 16. For each sex, the probabilities of survival increase as income increases corresponding to the type of benefit received. For example, the probability of a 65 year old male surviving to age 85 increases

from 29% for a GIS recipient to 51% if the clawback applies, and the corresponding probabilities for females are 49% and 65%.

The survival curves for each sex do not reflect much squaring as the mortality rates at the older ages follow a more gradual growth rather than an exponential growth. More of an expansion of the survival curves is seen for females than for males since females exhibit mortality rates that are more level at the advanced ages.

**Chart 16 OAS Beneficiary Survival Curves at Age 65 by Type of Benefit (2001)**

## VI. Mortality Improvement Rates

Annual mortality improvement rates were determined as a by-product of the derivation of the 2001 base year crude mortality rates. The four different methods to derive the 2001 base year crude rates were considered. Of these, three used regression methodologies and thus could produce improvement rates.

Method 4 was determined to be the best method to produce the mortality improvement rates, and these rates are shown below in Chart 17. Except at the very advanced ages, male annual mortality improvement rates have been greater than for females and exhibit a clearer declining pattern with age.

Further discussion about the different methods considered and resulting improvement rates are provided in Appendix C.

**Chart 17 OAS Beneficiary Annual Mortality Improvement Rates (2001)**

Annual mortality improvement rates can be used to project mortality rates in the future. However, it is very important to note that the measurement of annual mortality improvement rates over a short period of five years (1999-2003) as used for this study should be interpreted with caution because of the relatively high level of statistical variance in the results. The same also applies for improvement rates at very advanced ages (95 and over) due to low exposures and greater variation of results. Future OAS mortality studies using longer time periods may reveal different results.

Tables 21 and 22 show the average annual mortality improvement rates of the OAS program by subgroup based on the year 2001. The overall mortality improvement rates of the OAS program (3.2% for males and 1.8% for females) are greater than those of the benchmark (2.3% for males and 1.4% for females).

**Table 21 Male OAS Beneficiary Annual Mortality Improvement Rates (2001)**

Age Group	Overall OAS Program	Benchmark Mortality	Basic OAS with Clawback	Basic OAS without Clawback or GIS	OAS with GIS	Canada less Québec	Canada less Québec with CPP Retirement Benefit	Canada less Québec without CPP Retirement Benefit

**Table 22 Female OAS Beneficiary Annual Mortality Improvement Rates (2001)**

Age Group	Overall OAS Program	Benchmark Mortality	Basic OAS with Clawback	Basic OAS without Clawback or GIS	Basic OAS with GIS	Canada less Québec	Canada less Québec with CPP Retirement Benefit	Canada less Québec without CPP Retirement Benefit
	(%)	(%)	(%)	(%)	(%)	(%)	(%)	(%)
65-69	1.7	1.6	5.1	1.5	1.8	1.4	0.7	1.9
70-74	2.0	1.5	1.7	2.1	1.9	1.8	1.6	1.2
75-79	1.7	1.5	1.8	1.8	1.5	1.7	1.4	1.6
80-84	1.9	1.3	5.8	1.5	1.7	1.9	1.4	2.2
85-89	1.5	1.0	1.3	1.7	1.4	1.6	0.5	2.5
90-94	0.9	0.8	1.5	1.4	0.6	0.9	0.1	1.2
95-99	-0.1	0.6	0.8	-0.3	0.0	0.0	-2.4	0.7
100+	1.9	0.3	0.0	3.0	1.5	2.1	0.0	2.2
65+	1.8	1.4	3.0	1.7	1.6	1.6	1.1	1.8
65-84	1.8	1.5	3.3	1.7	1.7	1.7	1.2	1.7
85+	1.3	0.9	1.3	1.6	1.0	1.3	0.3	2.0

In general, annual mortality improvement rates for males have been greater than for females, and as a result the gap in mortality rates has been narrowing between the two sexes.

While male mortality improvement rates tend to diminish with age, this pattern is less noticeable for females. Both sexes have experienced greater improvement rates for those between the ages of 65 and 84 compared to those aged 85 and older. Annual mortality improvement rates for those in the age group 65 to 84 are 3.3% for males and 1.8% for females, while they are 1.5% for males and 1.3% for females for those 85 and older. At very advanced ages, annual mortality deterioration is observed for both sexes.

The analysis by type of OAS benefit reveals higher mortality improvement rates for those with a higher level of income. For example, males aged 65 and older who received a clawback-reduced OAS benefit experienced an annual improvement rate of 3.9% (3.0% for females) as compared to 2.9% (1.6% for females) to those who received both the OAS and income-tested GIS benefits.

## VII. Conclusion

The availability and quality of the administrative OAS beneficiaries database provide sufficient and reliable data upon which this study is based and allow an accurate measurement of the level and trend in mortality experienced by the oldest portion of the Canadian population. The study shows that the level of OAS mortality based on the year 2001 is higher than the projected mortality from the 1995-1997 Life Tables for Canada by about 7% for males and 6% for females.

In general, GIS recipients experience higher mortality and thus lower life expectancies relative to the overall OAS population. In comparison, those who receive clawback-reduced OAS benefits experience lower mortality and higher life expectancies. This may be explained by the association between high levels of income and improved health and quality of life.

## VIII. Appendices

### A. Supplemental Tables

**Table 23 OAS Beneficiary Deaths by Type of Benefit (1999-2003)**

Age	OAS with Clawback		OAS without Clawback or GIS		OAS with GIS		OAS Program

## B. Derivation of Annual Crude Mortality Rates

Three different methods that may be used to determine crude mortality rates are briefly described in this section. Of the three methods, the product-limit estimator method was chosen for this study as explained below.

### (i) *Balducci Method*

This method has traditionally been used by the OCA to study mortality. Its main advantage is that it simplifies exposure calculations to a certain extent, while its main disadvantage is that it may lose some accuracy at the advanced ages since exposures beyond the date of death are accounted for. While the Balducci method is still a valid method to calculate mortality rates, it is not based on statistical considerations.

### (ii) *Constant Force of Mortality Method*

Under this method, the force of mortality,  $\mu(x)$ , is assumed to be constant for each age ( $x$ ). This yields central rates of mortality at each age,  $m_x$ , defined as the ratio of deaths to exposures, which are constant and equal to  $\mu(x)$ . The crude mortality rates are subsequently derived from the formula  $q_x = 1 - e^{-m_x}$ . Though the crude mortality rates are simple to determine, it is debatable whether a constant force of mortality assumption is valid at the advanced ages.

### (iii) *Product-Limit Estimator (PLE) Method*

With the advent of calculators, and later, of computers, methods to estimate crude mortality rates have improved, and the PLE<sup>1</sup> method is such an example. This method produces survival rates from which mortality rates are easily obtained, whereas other methods produce mortality rates by taking ratios of deaths to exposures. The PLE method does not use exposures, but rather considers the product of survival probabilities across age intervals.

Between two consecutive ages, the one-year interval is divided into subintervals of half a month. For each subinterval  $i = 0, 1, 2, \dots, 23$ , an estimate is made of the number of people age  $(x) + \frac{i}{24}$  observed at the beginning of the subinterval  $i$ ,  $N_x(i)$ , and the number of deaths between ages  $(x) + \frac{i}{24}$  and  $(x) + \frac{(i+1)}{24}$  observed during the subinterval  $i$  to  $(i+1)$ ,  $D_x(i)$ . A survival rate  $p_x(i)$  for the subinterval is then estimated by the ratio of the number of people surviving the subinterval to the number of people observing at the beginning of the subinterval, such that  $p_x(i) = (N_x(i) - D_x(i)) / N_x(i)$ .

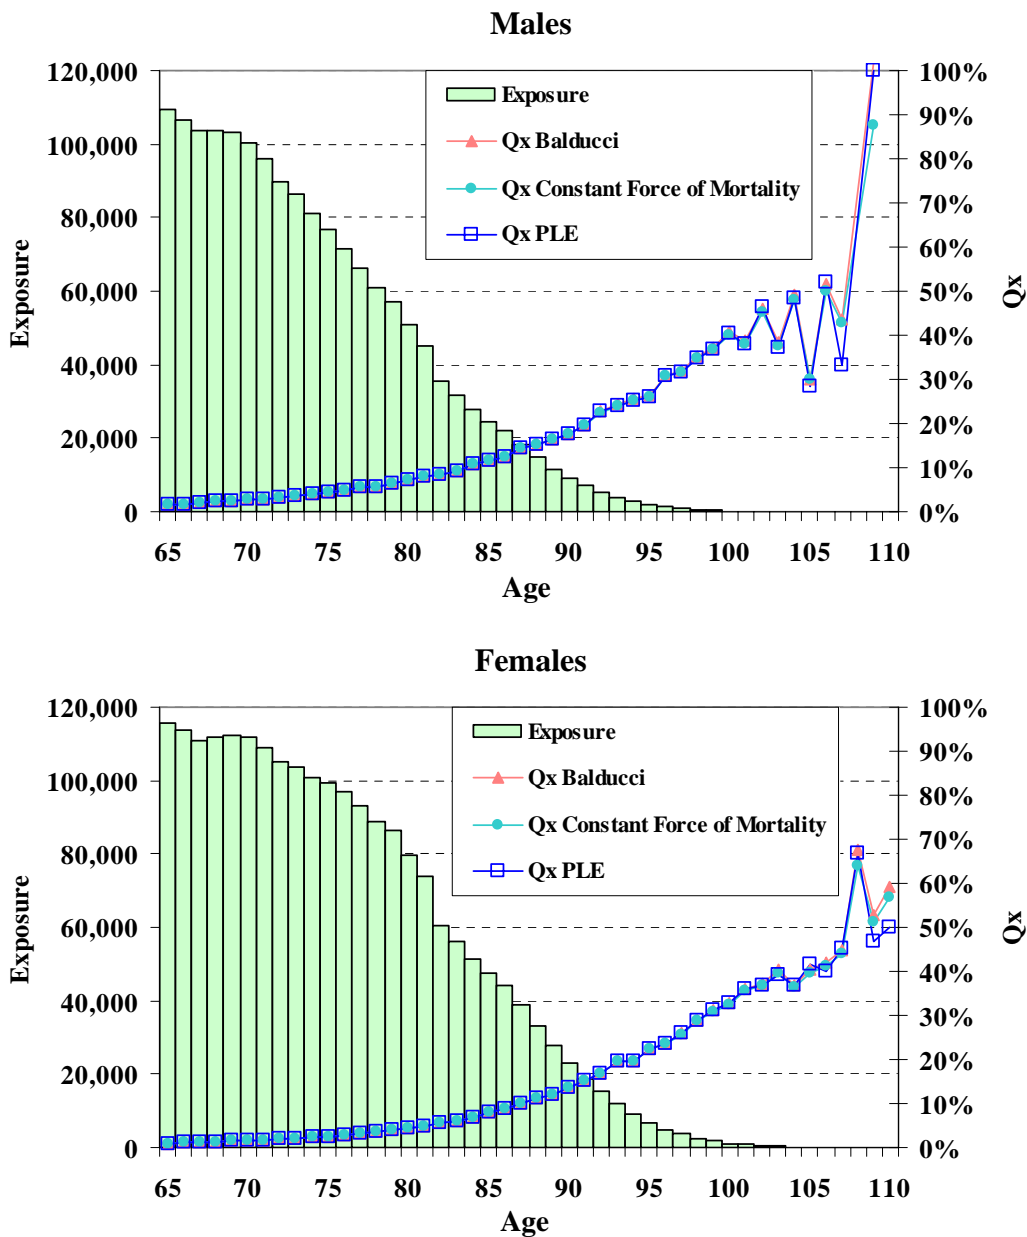

The annual crude survival rate,  $p_x$ , is then estimated as the product of the 24  $p_x(i)$  survival rates within the one-year age interval. Some adjustments are made for incomplete ages. For example, the adjustment at age 65 of  $p_{65}^{adj} \cong p_{65}^{24/23}$  was made to take into account the fact that the age of OAS entitlement is defined to be at the beginning of the month after the 65th birthday. For each age ( $x$ ), the annual crude mortality rate,  $q_x$ , is then determined simply as  $1 - p_x$ .

<sup>1</sup> Also referred to as the Kaplan-Meier Estimator.

The PLE method produces estimators that are more complex to generate and have higher variance, but that are said to be true maximum likelihood estimators (under certain conditions) of crude mortality rates.<sup>1</sup>

A comparison of the results produced by the three methods described above is shown in Chart 18. Except at the advanced ages, the three methods measure mortality rates at about the same level. The annual crude mortality rates in this study are derived from the PLE method because of its sound statistical basis and the fact that it does not require any particular mortality assumption.

### C. Derivation of 2001 Base Year Crude Mortality Rates

The 2001 base year crude mortality rates are based on the observation period spanning from 1999 to 2003. The use of five years of data reduces statistical fluctuations that may result if only one year of data were used. Four methods were developed to derive the base rates from the annual crude mortality rates over the five years. Among these four methods, three of them (Methods 2, 3, and 4) adjust the resulting rates by explicitly taking into account mortality improvements that are expected to be observed over the five-year period.

Methods 2, 3, and 4 all use least squares linear regression models in order to explicitly take into account mortality improvements. The use of least squares regression methodologies to produce base rates and improvement factors at the same time is not trivial. The use of least squares regression produces two sets of results: base mortality rates adjusted for mortality improvements and mortality improvement factors.

The following describes all four methods.

1. Method 1 is the Product-Limit Estimator method applied to the aggregated number of beneficiaries,  $N_x$ , and number of deaths,  $D_x$ , over the five-year period of the study. As compared to Method 2 (see below), its main drawback is that it does not account explicitly for multiplicative annual mortality improvement factors; however, since it is based on only five years of data, it produces values close to those obtained by Method 2.
2. Method 2 consists of five-year least squares regressions on the natural logarithm ( $\ln$ ) of the annual crude mortality rates performed separately for each possible combination of age, sex and subcategories. The least squares regressions allow for the derivation of the 2001 base year crude rates and the mortality improvement rates at the same time.

Five data points (one for each year from 1999 to 2003) are used to obtain a 2001 base year crude mortality rate for a particular age ( $x$ ), which accounts for a multiplicative mortality improvement factor (MMIF). The mortality improvement factor is simply  $1 - \text{MMIF}$ . For example, a MMIF of 0.97 results in a mortality improvement factor of 0.03 or 3%. The simplified mathematical model is:

$$q_x^{\text{year}} = q_x^{2001} * \text{MMIF}_x^{\text{year}-2001} \rightarrow \ln(q_x^{\text{year}}) = \ln(q_x^{2001}) + (\text{year}-2001) * \ln(\text{MMIF}_x),$$

where  $q_x^{\text{year}}$  is the crude mortality rate for a given year and age ( $x$ ) obtained via the Product-Limit Estimator method, as described earlier.

3. Method 3 consists of five-year and five-age least squares regressions to estimate a set of five central rates of mortality ( $m_x$ ) for any combination of age, sex and subcategories. Methods 3 and 4 both use twenty-five data points to produce different mortality rates for five successive ages while producing only one average mortality improvement factor for the corresponding quinquennial age group. Unlike the other three methods, Method 3 does not require the annual crude mortality rates since it produces the central rates of mortality from basic exposures

and deaths. For ages (x) between  $x_0$  and  $x_{0+4}$  (where  $x_0$  is age 65, 70, 75, etc.) the mathematical model uses a multiplicative survival improvement factor (MSIF) for each age group. The crude survival rates,  $p_x$ , are transformed into mortality rates,  $q_x$ , in order to compute the resulting mortality improvement factors. The model is of the form:

$$p_x^{\text{year}} = p_x^{2001} * (\text{MSIF}_{x_0})^{\text{year}-2001} \rightarrow -\ln(p_x^{\text{year}}) = -\ln(p_x^{2001}) - (\text{year}-2001) * \ln(\text{MSIF}_{x_0}),$$

where  $p_x^{\text{year}}$  is the crude survival rate for a given year and age (x) obtained by the Product-Limit Estimator method, as described earlier.

Under a constant force of mortality assumption, this simplifies to:

$$m_x^{\text{year}} = m_x^{2001} - (\text{year}-2001) * \ln(\text{MSIF}_{x_0})$$

$$D_x^{\text{year}} / E_x^{\text{year}} = m_x^{2001} - (\text{year}-2001) * \ln(\text{MSIF}_{x_0}),$$

where  $D_x$  and  $E_x$  are the number of deaths and exposures, respectively, for age (x). This method produces five central rates of mortality for any combination of subcategories and one MSIF for each quinquennial age group.

4. Method 4 is a combination of Methods 2 and 3. It is similar to Method 2 except that it is applied to five different ages at the same time and has some characteristics of Method 3 in that it uses annual crude mortality rates instead of central rates of mortality and produces one MMIF for each quinquennial group.

### *Conclusion*

In summary, one of the problems with Method 2 is that it uses five data points to produce two values for a given age (x), a 2001 base year crude mortality rate and a MMIF. As a consequence, even though the 2001 base year crude rates obtained compared well to those produced under the other methods, the resultant MMIFs showed a wider fluctuation from age to age. As such, Methods 3 and 4 were considered superior because they produced six values while using twenty-five data points.

Although the four methods produce close results, Method 4 was chosen to estimate the 2001 base year crude mortality rates. Method 1 was not selected since it does not produce mortality improvement factors. Method 2 was not selected because, when compared to Methods 3 and 4, the improvement factors are less statistically significant when computed by age group since fewer data points are used. Although both Methods 3 and 4 are very good, Method 4 was ultimately selected because it uses annual crude rates based on product limit estimators.

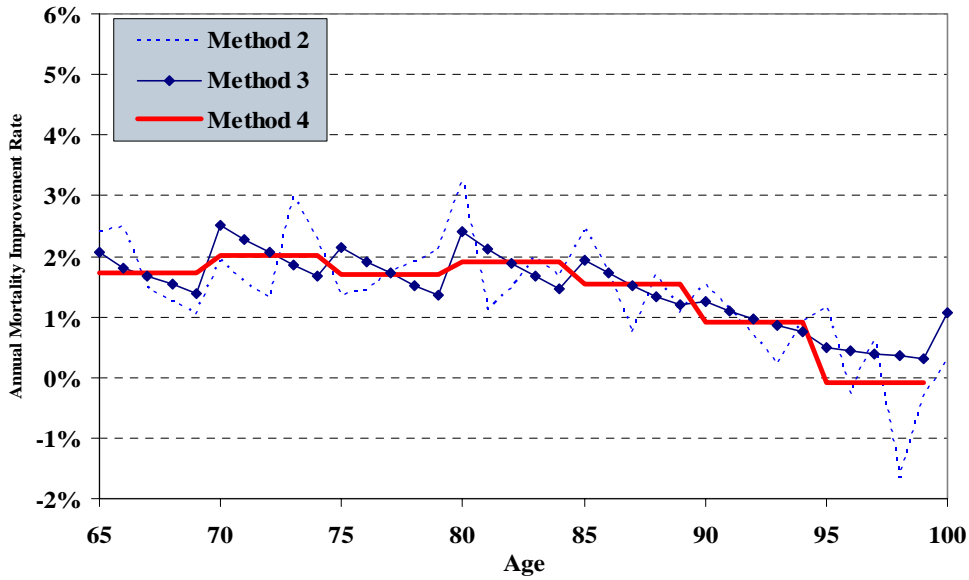

A comparison of the annual mortality improvement rates produced by each regression-based method (Methods 2, 3, and 4) is shown in Chart 19. All three methods show that, except at the very advanced ages, male improvement rates have been greater for females and exhibit a clearer declining pattern with age.

## D. Derivation of the Extension of Graduated Mortality Rates to Age 120

Two possible functions, one logistic and one exponential, were considered to extend the graduated rates from age 100 to age 120. Both are based on the use of linear relationships between  $\ln(q_x/q_{x-1})$  and age (x), i.e.,  $b + m(x)$ , such that  $q_x = q_{x-1} * e^{b+m(x)}$ .

The curves of  $\ln(q_x/q_{x-1})$  versus (x) based on the 2001 base year graduated mortality rates show a quasi-linear relationship between the ages 90 and 100. As such, it was decided to extend the mortality rates to age 120 using the same progression. The linear regressions are used to obtain linear parameters b and m for males and females separately. Extending the “natural” log-linear curves up to age 120, produced a resulting  $q_x$  curve that resembled an s-shaped curve familiar to the logistic family of curves.

The second method uses the natural progression of the log-linear relationships up to age 100 and then continues with a new log-linear curve up to age 120 with the additional constraint that the age 120 mortality rates would reach 1. The resulting  $q_x$  curve is of the exponential form.

After analyzing a pattern of mortality at the advanced ages, it was decided that the logistic function was a better choice since it better reflects rising mortality at diminishing rates at the advanced ages. The logistic and exponential projections of mortality for both sexes are shown in Chart 20.
